I am relatively new to the world of multiple linear regression (MLR) and am having trouble managing the data set I am working on. Basically I have a bunch of independent variables (X) which I predict the outcome (Y) for, and the model should be a function of those and some "time" variable. To make things even more complicated, the model is based on a subset of time period (there will be only one data set for each time period, which means I need to have different models for different time periods). My problem is, I don't want to forget one of the models, in case I want to analyze the results, and I want to be able to see which variables (X) are significant for the model. In

R this can be done by using `summary(model)`. How can I achieve this in Python? Is there some package that allows this? Here is what I have done so far:

For each time period I have a model that predicts one Y variable from one X variable. I am currently using a simple linear regression, because I could not find any linear model that would fit my data, no matter what I tried. I am using Python 3.4.1, with the statsmodels library, in case that matters. This is how the data look like:

Time	X1	X2	X3	X4	Y
0	4	3	4	5	0.5
1	5	2	4	5	0.7
2	3	4	3	4	0.4

I'm using the following code to predict the values of Y: `regression_model = smf.ols(formula = 'Y ~ X1', data = dataset)` I run

Unlimited nintendo ds games. Enjoy! is it possible to download ds games online? Yes it is, with any one of these great sites you can play your favorite
