By Edmond Tran. – elgin tp 3000 driver download. Cochlear implantation in the anterior cranial fossa: a novel approach for pediatric hearing loss. Patients with severe to profound hearing loss can now be expected to benefit from cochlear implantation. However, existing techniques for cochlear implantation (Cochleostomy and Cochleostomy with myringotomy) are not without complication. This paper describes a novel, simpler technique for cochlear implantation that involves small myringotomies in the anterior cranial fossa, followed by complete obliteration of the myringotomy site using a gelatin sponge. The aim of the study is to evaluate the technique. All patients who had cochlear implantation between November 2012 and January 2014 using the anterior cranial fossa technique were recruited into the study. A retrospective review of patient demographics, surgical and post-operative details was undertaken. Seven patients underwent cochlear implantation using the anterior cranial fossa technique. The average age at surgery was 14 months (range 3 to 28). All patients had congenital deafness, with no other cochlear anomalies. Median number of surgeries performed to date was 1.5. All patients had their implants placed successfully. A single cochleostomy incision was made at the level of the round window niche. The incision was followed by a myringotomy on the anterior and inferior aspects of the round window, with a small channel created for placement of the electrode array. The myringotomy was then completely obliterated with a gelatin sponge. Mean duration of surgery was 1.5 hours (range 1.25 to 2 hours). The patient was discharged the same day. All patients' initial auditory response thresholds were within the 2d92ce491b
