ver.A number of operations are required to treat a rock formation for the purpose of stimulating production of hydrocarbons.
Most of the operations are done at locations near the surface. The rock formations are usually stimulated using high pressure
water injected into a bore hole. A variety of stimulation methods are available and widely practiced, including water injection,
acid injection, foaming, and fracture acidizing. Acid injection is typically used in the initial stages of a reservoir stimulation
project in which the cost of the project is no higher than that associated with water injection. The problem with acid injection is
that there is a risk of acidizing a formation without stimulating the formation
